Dumpper V.80.8 26 Q: How do I find the most commonly used postfix operations? I have got a set of algorithms written in C. In my project, some of these algorithms will be used for debugging (just print the algorithm's workflow and see how it goes). What is the best way to find most commonly used postfix, prefix, and unary operations for a given type? For example: In the case of finding operators for floating point type, I want to find: + - \* / A: I'd suggest to look at the asymptotic cost of these operations. Minimal cost for a floating-point type: + - \* / cost = 1 for multiplications, cost = log(n) for additions, cost = log(n) + n for subtractions, and cost = n for a division. (This is the cost analysis for single-precision floating-point numbers. It's not complicated to generalize the cost analysis for double-precision floating-point numbers or complex numbers.) The cost analysis also shows that the most expensive operation is division. It also shows that comparison is always cheaper than the corresponding arithmetic operation, which includes the case when a condition for the comparison is a value of the same type, so that the comparison will be free of cost in practice. Other operations with a reasonably good cost analysis: and, or, not, left-shift, right-shift, bitwise operations, especially bitwise-xor. There are some other operations with acceptable cost analysis, but that are not as commonly used: Negative numbers. Negative-zero numbers. Overflow for operations that have to perform overflow-checking. There are lots of other operations. For example, computation of square roots is extremely complex. In particular, there are no efficient algorithms for it, because long division 3da54e8ca3
